

Laser diode of CD player

Overview

The laser assembly in a CD player includes several parts: the laser diode that produces the beam, the focusing lens on the pickup head, photodiodes that detect the reflected light, and the sled mechanism that moves the assembly across the disc. The laser assembly, known as the optical pickup unit (OPU), is responsible for reading the microscopic pits on a CD's surface. When this component fails, common symptoms appear—such as the player displaying “NO DISC,” skipping tracks, or failing to spin the disc. The reflected beam from the CD takes a slightly different path, and shoots back towards the prism. The prism deflects this reflected beam back into the laser diode where a. This guide will show you how to replace the laser mechanism on a CD player. These properties are important for a compact disc because the music data is grouped. For a 5 mW laser diode, the resulting power density on this facet can be in excess of 600 MW (that is mega-watts) per square meter! Sounds impressive, doesn't it?

At the CD, the spot is even smaller which for the same power would result in even higher densities. However, this is more than offset by.
