

# Quantity of various types of server racks in cold aisle

## Overview

The hot and cold aisles in the data center are part of an energy-efficient layout for server racks and other computing equipment. The goal of a hot/cold aisle configuration is to manage airflow in a way that conserves energy and lowers cooling costs. In its simplest form, hot aisle/cold aisle data center design involves lining up server racks in alternate rows. The principal reason for configuring data centers with hot and cold aisles is to manage heating, ventilation and air conditioning (HVAC) systems in the most effective way to conserve energy. Data centers that have not been retrofitted with hot/cold aisles are likely to use more energy. Considering how energy costs have increased in recent years, it is important to implement a hot and cold aisle containment layout. Four best practices when implementing a hot and cold aisle containment layout are the following: 1. Raise the floor 1.5 feet so air conditioning equipment can push air through that space. 2. Deploy high cubic-foot-per-minute rack grills that have airflow output in the range of 600 CFM. 3. Place devices with side or top exhausts in their own part of the aisle. Equipment racks in data centers are used to secure servers, communications equipment, power supplies and air-handling equipment. Data centers usually have cooling units that must be strategically positioned for optimum airflow. When building a new data center, hot/cold aisles can be part of the design from the start. When upgrading a legacy data center to a modern hot/cold aisle arrangement, the process is more complicated. Designers should do a cost-benefit analysis to determine if the investment will generate sufficient savings and return on investment. Among the factors.
